It's a common feature to be able to send and recieve text messages from your phone using only a few buttons. This project uses the MCU's USARTs to send and recieve text messages and provides these features: - Remote control of the MCU and ability to recieve messages - Send and recieve messages on a certain frequency (or group of frequencies) - Text message size to accommodate any messages you want to send - Text message recieve delays - Customizable data and message formats User is able to connect multiple modules to a single output pin (think of it as one of your MCUs USARTs) There are also two different ways to connect modules to this application: - serial pins/outputs - group pins/outputs VCCS_MPL 1.01_VC2A_CP 1.01 ============ This is the newest version of the MPL programming library that I have released, I'm not sure if it is worth a purchase but if you need the latest version (1.01) it is available for $20 (USD) for the first one million downloads. Included is: - AVC-3210.s (complete code) - TMS34021.s (complete code) - Support for C/C++/VHDL This version of the MPL library is not my original library, I had no reason to go back and update it so it is not the best version out there (for C language), but it will do. I will be updating it again with a more optimized code later on but this version is working well with the source codes I use for my projects and

is also backwards compatible with the previous library. P.S. This version contains only the required codes to compile my programs that use the TMS34021 and AVR32 family of MCUs. The previous version of the library can be found here: Root of all evil? An AVR 8-bit MCU to enable a robot with no central processing unit Version 1.6.1 ================= Initial version. Included: - ASCIIModule.h - ASCIIModule.h.in - \avr32/include/avr32/program.
